

# How will the study work?

Half of the participants enrolled in the study will receive an investigational study medication.

The other half will receive a placebo (a dummy medication), which contains no active ingredient.

This helps confirm that any changes we may see are due to the investigational study medication.

The investigational study medication and placebo will be given as a 60-minute intravenous infusion (which you may hear referred to as an 'IV' or 'drip') every 4 weeks. This means that a needle is inserted directly into a vein.

**You, your loved one and the study team will not know who is receiving the investigational study medication and who is receiving a placebo.**

The study doctor can find out which the participant is receiving in the case of a medical emergency.
